Wrong guidelines: why and how often they occur

Primiano Iannone,[1] Nicola Montano,[2] Monica Minardi,[3] James Doyle,[3] Paolo Cavagnaro,[4] Antonino Cartabellotta[5]

"Unfortunately, depending on how their reliability is measured, up to 50% of guidelines can be considered untrustworthy. This carries serious consequences for patients' safety, resource use and health economics burden."

EBM 2017;22:1-3

Wrong guidelines: why and how often they occur

Primiano Iannone,[1] Nicola Montano,[2] Monica Minardi,[3] James Doyle,[3] Paolo Cavagnaro,[4] Antonino Cartabellotta[5]

"guideline reliability is largely over-stated, and guidelines still suffer methodological flaws, limited panel composition and conflicts of interests, making their conclusions often untrustworthy. Even when evidence-based methodology is claimed, it is often not fully adopted and the 'evidence-based quality mark' gets misappropriated by vested interests"

EBM 2017;22:1-3

We recommend

- those involved in the conduct of clinical research (universities/research institutions/industry), should provide training in research methods and the use of statistics in evaluating the benefits and harms of medicines for research staff across all career stages as part of their continuing professional development
- similar courses should be provided for healthcare professionals by universities or CPD programmes
- existing courses should also be reviewed and, where necessary, new courses should be established to accommodate the full range of evidence-generating approaches for assessing the benefits and harms of medicines

Universities and research institutions should play a greater role in ensuring that the research they host is portrayed accurately in the media.

“It’s a statistically significant finding”

There are always 3 possibilities that must be considered:

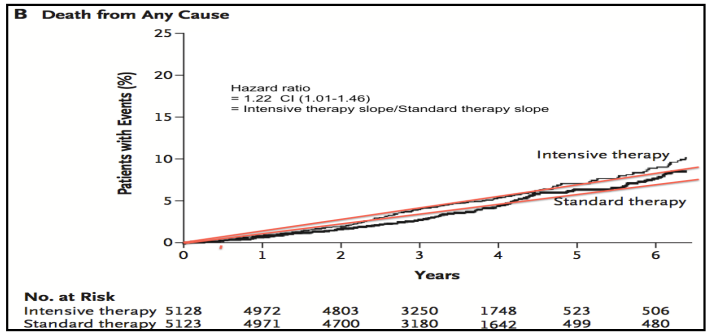
1. The observed difference was due to chance
2. The observed difference was due to confounding or other source of bias
3. If neither 1 nor 2 is believed to have caused the difference, then by simple elimination, it is inferred that the treatment caused it

Similar but different relatives

Relative risk/risk ratio (RR) - ratio of two probabilities (%) at one point in time - treatment/ control

- eg 8% vs 10% - RR = 8/10 = 0.8
- most useful in low probability events

Hazards ratio (HR) - ratio of two hazard rates (slopes) over a time period



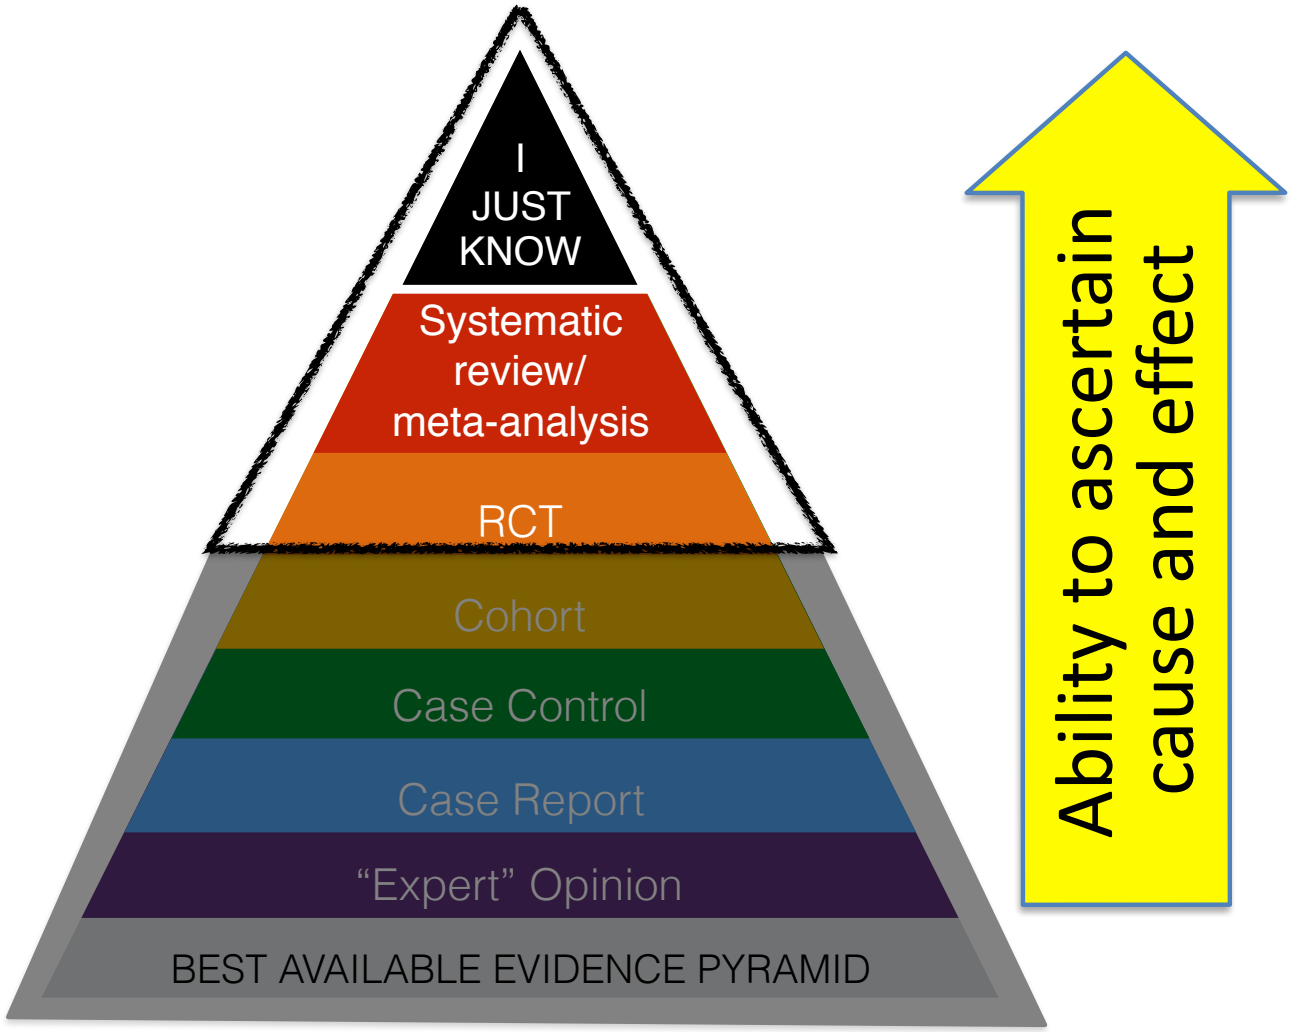
Odds ratio (OR) - ratio of two odds (25/1) - typically used in case-control studies - typically the incidence is not known

OR is a reasonable estimate of the **RR** if a disease is "rare" <~15% but treating an **OR** as if it were an accurate estimate of the **RR** will typically overestimate both the likely benefits and harms of treatment

Healthcare should be all about
Figuring out AND Explaining about

The Chance of Something Happening
WITH NO TREATMENT
VS
The Chance of Something Happening
WITH TREATMENT
over a period of time

It's really THAT simple



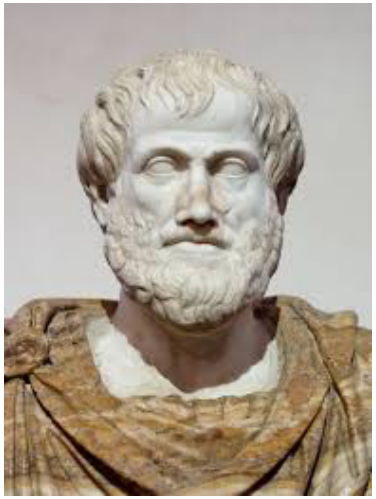
Need different evidence for different questions

It’s a Mindset

SCIENCE: NOT JUST FOR SCIENTISTS

We believe *that science is a human endeavour; it’s a way to ask questions about the world and test them out. It’s not just a list of facts;* ***it’s a mindset*** *owned by anyone who approaches the world in an* ***open-minded, sceptical, logical, systematic, empirically-oriented, tentative and curious way.*** *It applies in the natural and social sciences, as well as technology, engineering and mathematics.*

“For the things we have to learn before we can do them, we learn by doing them.”
— Aristotle, The Nicomachean Ethics



You may already know many of the concepts, which is great, because you will get to practice them and maybe learn some interesting therapeutics

Clinical Questions (PICO)

Patient
  Description of the most important characteristics of the patient or target disorder
Intervention
  What do you want to do for the patient?
  Could include exposure, diagnostic test, prognostic factor, surgery, therapy or patient's perception
Comparator(s)
  Relevant alternative(s) most often considered for this type of patient
Outcome
  Clinical outcome of interest to you and your patient

Effects of Intensive Glucose Lowering in Type 2 Diabetes

The Action to Control Cardiovascular Risk in Diabetes Study Group*

ABSTRACT

BACKGROUND

Epidemiologic studies have shown a relationship between glycated hemoglobin levels and cardiovascular events in patients with type 2 diabetes. We investigated whether intensive therapy to target normal glycated hemoglobin levels would reduce cardiovascular events in patients with type 2 diabetes who had either established cardiovascular disease or additional cardiovascular risk factors.

METHODS

In this randomized study, 10,251 patients (mean age, 62.2 years) with a median glycated hemoglobin level of 8.1% were assigned to receive intensive therapy (targeting a glycated hemoglobin level below 6.0%) or standard therapy (targeting a level from 7.0 to 7.9%). Of these patients, 38% were women, and 35% had had a previous cardiovascular event. The primary outcome was a composite of nonfatal myocardial infarction, nonfatal stroke, or death from cardiovascular causes. The finding of

therapy after a mean of 3.5 years of follow-up.

therapy group (hazard ratio, 1.22; 95% CI, 1.01 to 1.46; P=0.04). Hypoglycemia requiring assistance and weight gain of more than 10 kg were more frequent in the intensive-therapy group (P<0.001).

CONCLUSIONS

As compared with standard therapy, the use of intensive therapy to target normal glycated hemoglobin levels for 3.5 years increased mortality and did not significantly reduce major cardiovascular events. These findings identify a previously

ITT analysis

(if randomized then analyzed)

- intuitively one would want to exclude these people from the evaluation BUT
- excluding these people could lead to a randomization issue - now it is no longer truly randomized
- the protocol violations may be **secondary to the intervention or disease severity**
- you lose power if you exclude people
- exclusions could lead to a bias
- including all people is **more like practice**
- a per-protocol analysis - only analyze those who adhered to the protocol - is actually **closer to the true efficacy** of the treatment HOWEVER an **ITT is a more conservative estimate**

Lost to follow-up

Could be a problem if:

the % of people lost to follow-up is greater than the absolute effect

OR

the % lost is quite different in one arm

Serious adverse event	2.2	1.6		
Weight gain >10kg	27.8	14.1		

Combined CVD (death, MI, CHF, angina, stroke)

	Combined CVD	No CVD	Total (n)
Doxazosin	1592 a	7475 b	9067 a+b
Chlorthalidone	2245 c	13023 d	15268 c+d

Chlorthalidone = Control
Doxazosin = Experimental

Control event rate (CER) = c/c+d = 2245 / 15268 = **0.147 = 14.7%**

Experimental event rate (EER) = a/a+b = 1592 / 9067 = **0.176 = 17.6%**

Relative Risk (RR) * = EER / CER = (a/a+b) / (c/c+d) = **17.6%** / **14.7%** = **1.20**

Relative Risk Increase (RRI) = EER – CER/CER = (**17.6%** - **14.7%**) / **14.7%** = **20%**

Risk Difference (RD) = Absolute Risk Increase (ARI) = EER – CER = **17.6 – 14.7 = 2.9%**

NNH = 100/ARR = **100 / 2.9 = 34.5 ≈ 35**

Therefore, you would harm one person for every **35** you treat with Doxazosin instead of Chlorthalidone.

The effect of Risedronate on the risk of hip fracture in elderly women

- 6197 randomized to Risedronate and 137 had a hip fracture.
- 3134 randomized to Placebo and 95 had a hip fracture.

EER: 137/6197 = 2.21%

CER: 95/3134 = 3.03%

- **Note**: Or use the Kaplan-Meier survival curves to estimate which were CER 3.9% & EER 2.8%.

- What is the relative risk reduction of hip fracture for those on Risedronate?

RR: 2.8 / 3.9 = 0.72
RRR: 1-0.72 = 0.28 = 28%

- What is the number of patients who would have to receive Risedronate (the NNT) to prevent one hip fracture in high risk women over three years?

AR: 3.9 – 2.8 = 1.1%
NNT: 100 / 1.1 = 91

RR : 2.21 / 3.03 = 0.73, RRR = 1 – 0.73 = 0.27 or 27%
AR: 3.03 – 2.21 = 0.82, NNT: 100 / 0.82 = 122

- “Garbage in = Garbage out"
- “Are MAs a form of medical fake news?”

"Anybody who publishes a high-quality large scale meta-analysis should in my opinion, receive a **gold medal, a large promotion, and a long, fully paid vacation.** Such a research synthesis can be an immensely valuable scholarly contribution that brings **order to confusion**, helps set a future research agenda, and at the same time gives the **best evidence-based practice advice**"

Geoff Cumming

Meta-Analyses Should Not Tell Us What We Already Know or Obscure What We Should Remember

Meta-analyses should provide insights that are superior to those provided by a narrative summary of the data. If large-scale trials of 3 different β-blockers (bisoprolol, carvedilol, and metoprolol) for heart failure each report a nearly identical 35% reduction of all-cause mortality, little purpose would be served by performing a meta-analysis of the 3 trials. Not only would such a meta-analysis not add any new information, but also its results would not necessarily apply to other β-blockers (eg, bucindolol and nebivolol). Many meta-analyses only confirm existing knowledge and may conceal meaningful differences that can best be understood descriptively, rather than mathematically.

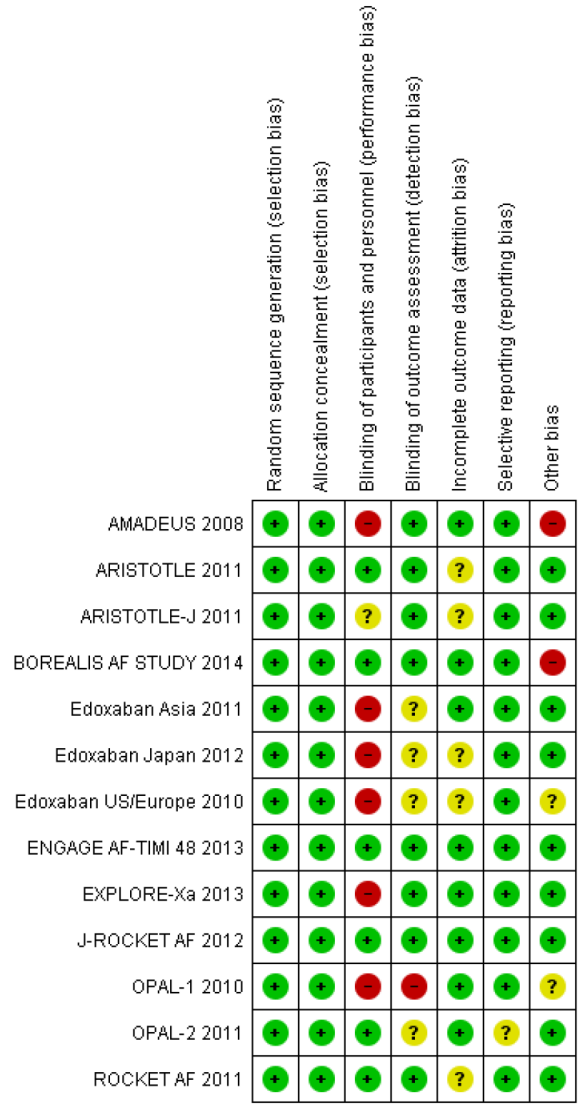
Summary of Findings

Factor Xa inhibitors compared with vitamin K antagonists for preventing stroke and other systemic embolic events in patient with atrial fibrillation

Patient or population: people with atrial fibrillation deemed eligible for long-term anticoagulant treatment
Settings: hospital-based setting
Intervention: factor Xa inhibitor[1]
Comparison: dose-adjusted vitamin K antagonist[2]

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				
	Warfarin	Factor Xa inhibitors				
Stroke and other systemic embolic events Follow-up: 12 weeks to 2.8 years	**34 per 1000**	**32 per 1000** (33 to 28)	**OR 0.89** (0.82 to 0.97)	67477 (13)	⊕⊕⊕⊕ **high**	Most data (90%) from studies of apixaban, edoxaban and rivaroxaban
All strokes Follow-up: 12 weeks to 2.8 years	**30 per 1000**	**28 per 1000** (29 to 24)	**OR 0.89** (0.81 to 0.97)	67449 (13)	⊕⊕⊕⊕ **high**	Most data (90%) from studies of apixaban, edoxaban rivaroxaban
Major bleedings Follow-up: 12 weeks to 2.8 years	**51 per 1000**	**41 per 1000** (43 to 38)	**OR 0.78** (0.73 to 0.84)	67396 (13)	⊕⊕⊕◯ **moderate**[3]	Most data (90%) from studies of apixaban, edoxaban and rivaroxaban
Intracranial haemorrhages Follow-up: 12 weeks to 2.8 years	**13 per 1000**	**7 per 1000** (8 to 6)	**OR 0.50** (0.42 to 0.59)	66259 (12)	⊕⊕⊕⊕ **high**[4]	Most data (90%) from studies of apixaban, edoxaban and rivaroxaban

Author's assessment of the risk of bias



Characteristics of Studies

WOSCOPS

Methods	Randomised trial.	
Participants	6595 men with hypercholesterolaemia based in Scotland aged 45-64 (mean age 55). < 10% with clinical evidence of CVD	
Interventions	40 mg pravastatin versus placebo; follow-up 4.9 years.	
Outcomes	Primary outcome: composite of non-fatal MI and CHD death. Single outcomes included total mortality, fatal CVD events, cholesterol, revascularisations, non-fatal MI and CHD death and adverse events	
Notes		
Risk of bias		
Bias	**Authors' judgement**	**Support for judgement**
Random sequence generation (selection bias)	Low risk	Blocks of random numbers and treatment assigned randomly
Allocation concealment (selection bias)	Low risk	All trial personnel remained unaware of the participant's treatment assignment throughout the study
Blinding (performance bias and detection bias) All outcomes	Low risk	Double-blind: participants and personnel
Incomplete outcome data (attrition bias) All outcomes	Low risk	ITT used, 30% drop-outs reported
Selective reporting (reporting bias)	Low risk	
Other bias	Unclear risk	Funded by pharmaceutical industry

Data and Analyses

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Total Mortality	13	48060	Odds Ratio (M-H, Fixed, 95% CI)	0.86 [0.79, 0.94]
2 Total Number of CHD Events	14	48049	Risk Ratio (M-H, Fixed, 95% CI)	0.73 [0.67, 0.80]

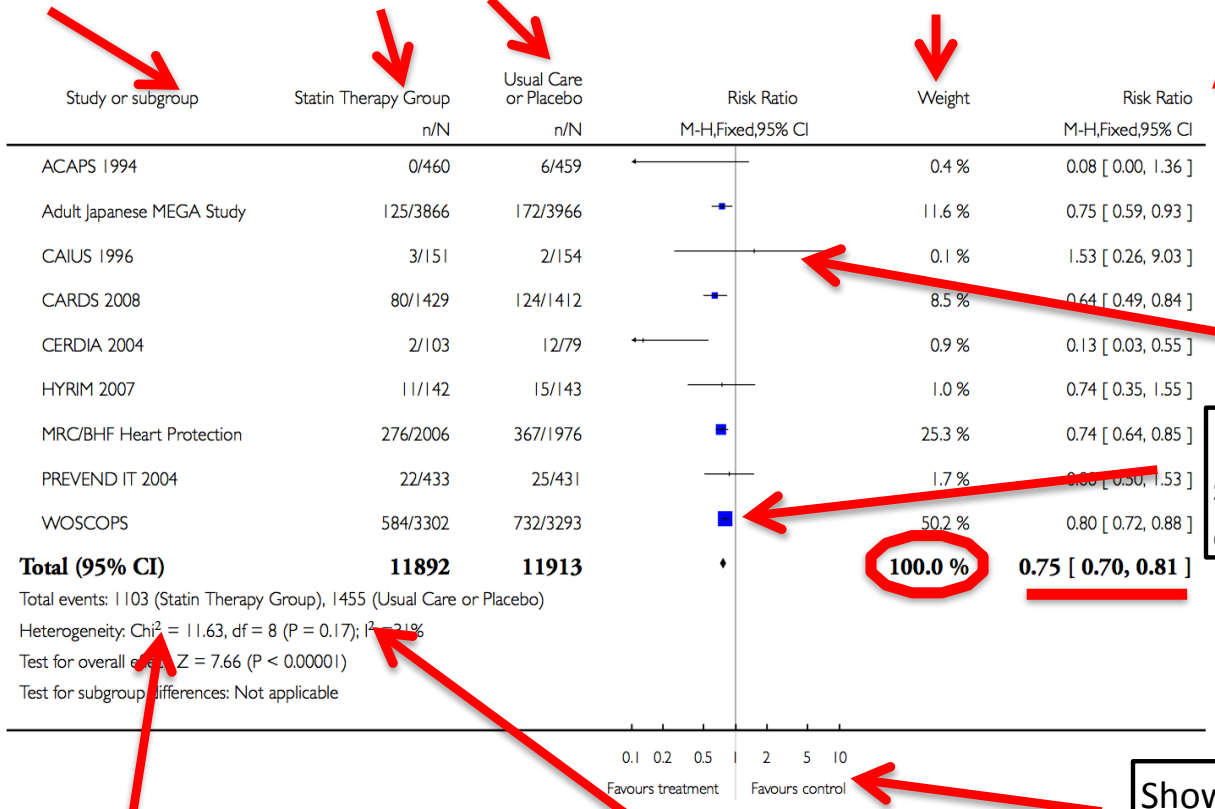
Mantel–Haenszel - statistical method
Random (assumes the studies are different) is more conservative than fixed (assumes trials are the same)

Included studies (ideally would have citation)

Includes the number of events & total included in each group

How much each study contributes (weight)

The actual (numeric) results for each study



Tiny square= small study

Big square= Big study and/or lots of events

Heterogeneity given & I^2 stat available

Final numbers of events and total included in each arm (can do “cheater” NNT)

Shows what side is “better” for treatment or control

CD004816 2013

Another common Forest plot “look”

How confidence intervals become confusion intervals

James McCormack[1], Ben Vandermeer[2] and G Michael Allan[3*]

BMC Medical Research Methodology 2013;13:134

Do statins reduce mortality in primary prevention?

Studer et al.: “reduced risks of overall and cardiac mortality”**YES**

Thavendiranathan et al.: [does not decrease]”overall mortality”**NO**

Mills et al.: “an important role in preventing all-cause mortality”**YES**

Brugts et al.: “associated with significantly improved survival”**YES**

Ray et al.: “did not find evidence for the benefit … on all-cause mortality”**NO**

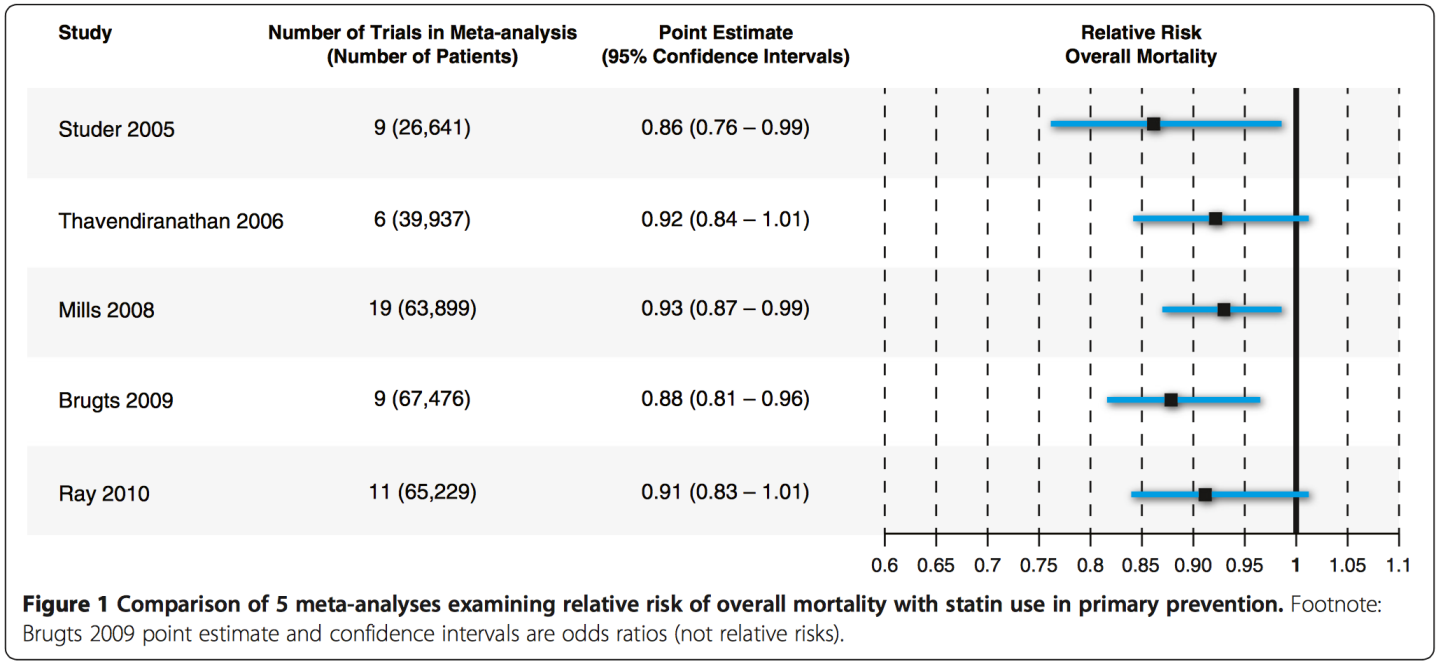

Figure 1 Comparison of 5 meta-analyses examining relative risk of overall mortality with statin use in primary prevention. Footnote: Brugts 2009 point estimate and confidence intervals are odds ratios (not relative risks).

Statistical Heterogeneity

Poor overlap in confidence intervals of individual generally indicates the presence of statistical heterogeneity

Best way to test: I^2

Rule of thumb to interpreting I^2:

- 0% - no heterogeneity
- 25% - low
- 50% - moderate
- 75% - high

Significant Heterogeneity

Differences between studies seem to exist

May be invalid to pool results and generate a single summary result

Need to explore sources of heterogeneity:

- Did they pool the correct effect measure?
  - Relative effect measure (HR, OR, RR) best for meta-analysis
- Sensitivity & subgroup analysis
- May be from differences in: Methods, patient inclusion/exclusion, intervention, control, outcome definition, duration

Statistical significance Yes; Heterogeneity No

Study or subgroup	donepezil N	Mean(SD)	placebo N	Mean(SD)	Mean Difference IV,Fixed,95% CI	Weight	Mean Difference IV,Fixed,95% CI

Beta-blockers vs other drugs in hypertension for MI

Lancet. 2005 Oct 29-Nov 4;366(9496):1545-53.

Effect size

Can refer to unstandardized effect sizes - the difference between group means, relative risk or odds ratio

Standardized effect sizes - such as ‘correlation’ or ‘Cohen’s d’ for when using different measurement scales

Often used as a summary statistic in meta-analysis when trials looked at the same outcome but used different scales to measure that outcome

Effect Sizes

Comparison: 1 TCAs versus placebo

Outcome: 1 Depression symptoms at post-treatment

Study or subgroup	Treatment N	Mean(SD)	Control N	Mean(SD)	Std. Mean Difference IV,Random,95% CI	Weight	Std. Mean Difference IV,Random,95% CI
Barge-Schaapveld 2002	23	8.9 (6.2)	26	12.5 (6.3)		6.1 %	-0.57 [-1.14, 0.01]

Test for subgroup differences: Not applicable

(*Continued . . .*)

A Type of Effect Size

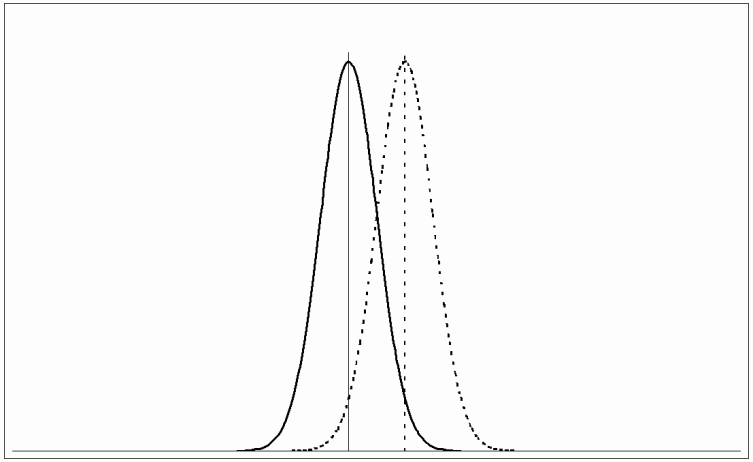
AKA Standardized Mean Difference

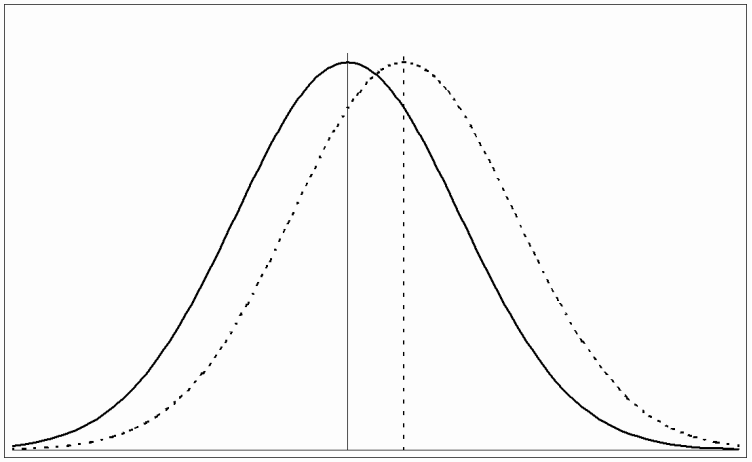
'Effect size' is simply a way of quantifying the size of the difference between two groups

Is an interpretation of the overlap of the results

An effect size of 0.5 means that the score of the AVERAGE person in the experimental group is 0.5 SD above the AVERAGE person in the control group

$$\text{Effect size} = \frac{\text{(Mean of the experimental group - Mean of the control group)}}{\text{Standard Deviation}}$$





Effect Size or SD above control	Description	Percentage of control group who would be below average person in experimental group
0.0		50%
0.1		54%
0.2	SMALL	58%
0.3		62%
0.4		66%
0.5	MEDIUM	69%
0.6		73%
0.7		76%
0.8	LARGE	79%
0.9		82%
1.0		84%
1.2	VERY LARGE	88%
1.4		92%
1.6		95%
1.8		96%
2.0	HUGE	98%

Interpreting effect sizes

Jacob Cohen - reluctantly suggested thresholds of 0.2, 0.5, and 0.8 as indicators of small, medium, and large effects - however he warns:

"The terms 'small', 'medium', and 'large' are relative . . . to each other . . . the definitions are arbitrary . . . these proposed conventions were set forth throughout with much diffidence, qualifications, and invitations not to employ them if possible. … The values chosen had no more reliable a basis than my own intuition."
